

Computation of the variance of the test statistic U_8^k based on the k'th imputation involves the following modification of Table 6b from the main document. The modification is shown in table below for $t_v = 12$.

Table 6b (modified) The n_v and n_{v1} are defined in **Table 6a**. Adding up the entries in the last column gives $V(\hat{U}_8^k)$ the variance of the test statistic $\hat{U}_8^k$

t_v	$n_v^k = n_v + \sum_{i=67}^{96} Y_i^k(t_v)$	$n_{v1}^k = n_{v1} + \sum_{i=67}^{96} Y_i^k(t_v)I(8 \leq r_i)$	$n_{v1}^k(n_v^k - n_{v1}^k)/(n_v^k)^2$
12	$29 + \sum_{i=67}^{96} Y_i^k(12)$	$20 + \sum_{i=67}^{96} Y_i^k(12)I(8 \leq r_i)$
